Dipole Model  
Diffractive Production  
W.W. Method  
 $\gamma - p$  Interaction  
 $\gamma - A$  Interaction

## UPC Collisions

## Peripheral Collisions

## Summary

- The production cross section can be written as

$$\sigma_{hh \rightarrow hx} \propto f_{a/h}(x_1, Q^2) \otimes f_{b/h}(x_2, Q^2) \otimes \hat{\sigma}(ab \rightarrow cd) \otimes D_{h/c}(z_c, \hat{Q}^2)$$

$f_p(x, Q^2) \rightarrow$  Parton Distribution Functions (PDF's): **CTEQ, MRST, GRV, ...**

$\hat{\sigma}(ab \rightarrow cd) \rightarrow$  partonic subprocess  $ab \rightarrow cd$ :  **$qq \rightarrow qq, q\bar{q} \rightarrow gg, gg \rightarrow gg, \dots$**

$D_{h/c}(z_c, \hat{Q}^2) \rightarrow$  fragmentations functions of hadron  $h$  from a parton  $c$ .

- $\gamma - p$  Interaction
- $\gamma - A$  Interaction

## UPC Collisions

## Peripheral Collisions

## Summary

## The Balitsky-Kovchegov Equation

$$\partial_Y \langle T(x, z) \rangle = \frac{\bar{\alpha}_s}{2\pi} \int d^2z \mathcal{M}(x, y, z) [\langle T(x, z) \rangle + \langle T(z, y) \rangle - \langle T(x, y) \rangle - \langle T(x, z) \rangle \langle T(z, y) \rangle]$$

- This equation evolves  $\langle T(x, y) \rangle$ , average over all the dipole amplitudes  $T(x, y)$ .
- The evolution variable is the rapidity  $Y \approx \ln 1/x$ .
- $\bar{\alpha}_s = \alpha_s N_c / \pi$  and  $\mathcal{M}(x, y, z) = \frac{(x-y)^2}{(x-z)^2(z-y)^2}$ .
- The photon splitting in the  $q\bar{q}$  pair with  $z$  and  $1-z$  fraction of light cone momentum.
- The quark or antiquark can emit soft gluons ( $z_2 \ll z_1$ ), which can also emit softer gluons.
- In the limit  $N_c \rightarrow \infty$ , these soft gluons can be considered as quark-antiquark pairs.

## UPC

Collisions

Peripheral

Collisions

Summary

- Complementary information on gluons distribution can be obtained

$r$  is the dipole separation.

$z(1-z)$  is the quark(antiquark) momentum fraction.

$b$  is the dipole-target impact parameter.

# Photo-Induced Interactions

- Diffractive production of vector mesons in hadron-hadron collisions.
- The process is characterized by large rapidity gaps in the final state.

- $Q^2 \rightarrow$  photon virtuality.
- $W^2 \rightarrow \gamma^* p$  center of mass energy.
- $t \rightarrow$  squared momentum transfer.

- We are interested in the first case: **Exclusive Photoproduction** ( $Q^2 \sim 0$ ),

$$p \otimes Pb \rightarrow Pb \otimes V \otimes p$$

# Weizsäcker-Williams Method

- Hadron-Hadron interaction  $\rightarrow$  photon-hadron interaction

- Thus, the hadron process can be written in a simpler way

$$\sigma_X = \frac{dN(\omega)}{d\omega} \otimes \sigma_X^\gamma(\omega)$$

where the equivalent photon flux is written as

$$\frac{dI(\omega)}{d\omega} = \frac{2q^2}{\pi} [\chi_{min} K_0(\chi_{min}) K_1(\chi_{min}) - \frac{1}{2} \chi_{min}^2 [K_1^2(\chi_{min}) - K_0^2(\chi_{min})]]$$

and  $\sigma_X^\gamma$  is the photoproduction cross section.

# The Photoproduction Cross Section

- For  $\gamma - p$  interaction, the forward scattering amplitude is given by

$$\text{Im } A_{\text{proton}}(x, t = 0) = \int \int \frac{d^2 r dz}{4\pi} (\psi_V^* \psi_\gamma)_T \sigma_{\text{dip}}^{\text{proton}}(x, r)$$

- $(\psi_V^* \psi_\gamma)_T$  - photon-meson wave function  $\rightarrow$  **Boosted Gaussian**;
- $\sigma_{\text{dip}}^{\text{proton}}(x, r)$  - dipole cross section  $\rightarrow$  **GBW** and **CGC** models;

- Then, the photoproduction cross section will be

$$\sigma(\gamma p \rightarrow V p) = \frac{|\text{Im } A_{\text{proton}}(x, t = 0)|^2}{16\pi B_V} \left(1 + \beta(\lambda_{\text{eff}})^2\right) R_g^2(\lambda_{\text{eff}})$$

- $x = (M_V^2 + Q^2) / (Q^2 + 2\omega\sqrt{s_{NN}})$  and  $B_V$  is the slope parameter;
- $\beta(\lambda_{\text{eff}}) = \frac{\text{Re } A_{\text{proton}}(x, t=0)}{\text{Im } A_{\text{proton}}(x, t=0)}$  restores the real contribution of the  $A_{\text{proton}}(x, t = 0)$ ;
- $R_g^2(\lambda_{\text{eff}})$  - skewedness effect.

# The Photoproduction Cross Section

- For  $\gamma - A$  interaction, the forward scattering amplitude is given by

$$\text{Im } A_{\text{nuc}}(x, t = 0) = \int \int \frac{d^2 r dz}{4\pi} (\psi_V^* \psi_\gamma)_T \sigma_{\text{dip}}^{\text{nuc}}(x, r)$$

where

$$\sigma_{\text{dip}}^{\text{nuc}}(x, r) = 2 \int d^2 b' \left\{ 1 - \exp \left[ -\frac{1}{2} T_A(b') \sigma_{\text{dip}}^{\text{proton}}(x, r) \right] \right\}$$

$b'$  is the photon-nuclei impact parameter.

$T_A(b')$  is the nuclear profile function;

- Then, the photoproduction cross section will be

$$\sigma(\gamma A \rightarrow VA) = \frac{|\text{Im } A_{\text{nuc}}(x, t=0)|^2}{16\pi} \left( 1 + \beta (\lambda_{\text{eff}})^2 \right) R_g^2(\lambda_{\text{eff}}) \int_{t_{\text{min}}}^{\infty} |F(t)|^2 dt$$

$F(t)$  - electromagnetic form factor and  $t_{\text{min}} = (M_V^2/2\omega\gamma)^2$ ;

Introduction

UPC  
Collisions

Peripheral  
Collisions

Experimental Data

b-Dependence

The eff. Photon Flux

The eff.  
Photonuclear Cross  
Section

Summary

- $R_{AA}$  as a function of  $p_T$  for mid-rapidity ( $|y| < 1$ )<sup>6</sup>.
- $\sqrt{s} = 200$  GeV for Au-Au and  $\sqrt{s} = 193$  GeV for U-U.
- More intense excess for **60%-80%** centrality bin.
- The  $J/\psi$  excess is still present for **40%-60%** centrality class.

<sup>6</sup>W. Zha (STAR Collaboration), Journal of Physics: Conference Series 779, 012039 (2017).

# b-Dependence Photon Flux

- For peripheral collisions  $\rightarrow N(\omega, b)$  with b-dependence <sup>7</sup>,

$$\frac{dN(\omega, b)}{d\omega db^2} = \frac{Z^2 \alpha_{qed}}{\pi^2 \omega} \left| \int d^2 k_T k_T^2 \frac{F(k)}{k^2} J_1(k_T b) \right|^2$$

- Yukawa potential+hard sphere (more realistic for lead) <sup>8</sup>,

$$F(k) = \frac{4\pi\rho_0}{Ak^3} [\sin(kR_A) - kR_A \cos(kR_A)] \left[ \frac{1}{1 + a^2 k^2} \right]$$

- $k^2 = (\omega/\gamma)^2 + k_{\perp}^2$ .
- $\rho_0 = 0.1385 \text{ fm}$  and  $a = 0.7 \text{ fm}$
- $A=208$  and  $R_A = 1.2A^{1/3} \text{ fm}$

<sup>7</sup> F. Krauss, M. Greiner and G. Soff, Prog. Part. Nucl. Phys. 39, 503, (1997)

<sup>8</sup> K. T. R. Davies and J. R. Nix, Phys. Rev. C14, 1977 (1976).

# Comparing the Form Factors

- Centrality classes and related impact parameters range:

Centrality Classes	Glauber Model		ALICE	
	$b_{\min}$ (fm)	$b_{\max}$ (fm)	$b_{\min}^{exp}$ (fm)	$b_{\max}^{exp}$ (fm)
30%-50%	7.77	10	8.55	11.04
50%-70%	10	11.87	11.04	13.05
70%-90%	11.87	13.47	13.05	14.96

- Analysis of the different form factors

Point Like (used in UPC)

- $F(k^2) = 1$

Dipole Form Factor

- $F_{\text{dip}}(k^2) = \frac{\Lambda^2}{\Lambda^2 + k^2}$

Woods-Saxon+Yukawa

- $F_{\text{WSY}}(k^2) = \frac{4\pi\rho_0}{Ak^3} [\sin(kR_{Pb}) - kR_{Pb}\cos(kR_{Pb})] \left[ \frac{1}{1+a^2k^2} \right]$

# The Effective Photon Flux

- Considering an effective photon flux <sup>9</sup>:

$$\sigma_X = \int \omega \frac{dN^{eff}(\omega)}{d\omega} \sigma_X(\omega)$$

- Hypothesis:** Only spectators interact coherently with the photon.

- In this scenario,  $\frac{dN^{eff}(\omega, b)}{d\omega}$  can be described as <sup>10</sup>

$$N^{eff}(\omega, b) = \frac{1}{A_{eff}(b)} \int N^{usual}(\omega, b_1) \theta(b_1 - R_A) \theta(R_A - b_2) d^2 b_2$$

- $A_{eff} = R_A^2 [\pi - 2\cos^{-1}(b/2R_A)] + (b/2) \sqrt{4R_A^2 - b^2}$  and  $b_1^2 = b^2 + b_2^2 + 2bb_2\cos(\alpha)$

<sup>9</sup> M. K. Gawenda and A. Szczurek, Phys. Rev. C93, 044912, (2016).

<sup>10</sup> M. B. Gay Ducati and S. Martins, Phys. Rev. D97, 116013, (2018).

# The Effective Photonuclear Cross Section

- The forward scattering amplitude is given by

$$\text{Im } \mathcal{A}_{nuc}(x, t = 0) = \int \frac{d^2 r dz}{4\pi} (\Psi_V^* \Psi_\gamma)_T \sigma_{dip}^{nucleus}(x, r)$$

where

$$\sigma_{dip}^{nucleus}(x, r) = 2 \int d^2 b' \left\{ 1 - \exp \left[ -\frac{1}{2} T_A(b') \sigma_{dip}^{proton}(x, r) \right] \right\}$$

- For consistency with the construction of  $N^{eff}(\omega, b)$ , restrict  $\sigma_{dip}^{nucleus}(x, r)$ :

$$\sigma_{dip}^{nucleus}(x, r) = 2 \int d^2 b_2 \Theta(b_1 - R_A) \left\{ 1 - \exp \left[ -\frac{1}{2} T_A(b_2) \sigma_{dip}^{proton}(x, r) \right] \right\}$$

- $b_1^2 = b^2 + b_2^2 + 2bb_2 \cos(\alpha)$ .

Photonuclear Cross

Section

Summary

# Our results for $d\sigma/dy$

- Essentially, three modification were considered

- b-dependence.
- Effective photon flux.
- Effective Photonuclear cross section.

- Comparing with ALICE data,

Average Rapidity Distribution:  $2.5 < y < 4.0$

GBW / CGC	$d\sigma_{J/\psi}^{\text{theo}}/dy [\mu\text{b}]$	$d\sigma_{J/\psi}^{\text{exp}}/dy [\mu\text{b}]$
30%-50%	134 / 85	$73 \pm 44^{+26}_{-27} \pm 10$
50%-70%	145 / 91	$58 \pm 16^{+8}_{-10} \pm 8$
70%-90%	138 / 87	$59 \pm 11^{+7}_{-10} \pm 8$

- Better agreement for CGC model.

# Our results for $R_{AA}$

- Black circles: only the b-dependence
  - Best agrees with the data only in the more peripheral region;
- Green losangle: b-dependence + effective photon flux
  - Better results were achieved for the more central classes;
- Blue triangle: All the three modifications was applied
  - A slight correction in direction to data in relation to last case;

$p_T < 0.3 \text{ GeV}/c$  ;  $2.5 < y < 4.0$  ; CGC model

## J/ψ photoproduction in peripheral collisions

- **Transition from ultra-peripheral to peripheral collisions:**
  - Need to account for the geometrical constraints of a given impact parameter
  - Modification of the photon flux / photonuclear cross section

**Scenario 1:** UPC like

**Scenario 2:** effective photon flux

**Scenario 3:** effective photon flux + photonuclear cross section

**IIM:** Color Glass Condensate approach

**GBW:** light cone dipole formalism

## Coherent $J/\psi$ cross section at forward rapidity

NEW

ALI-PREL-512349

- Ratio of the measurements at  $\sqrt{s_{\text{NN}}} = 5.02$  TeV and  $\sqrt{s_{\text{NN}}} = 2.76$  TeV shows no centrality dependence within uncertainties
- Fair agreement of the measured ratio to models (except GG-hs) within uncertainties

19

Quark Matter 2022 - A. Neagu

## The Effective Photon Flow

Fig. 1: Scheme of the interaction according to scenario 2.

- From the standard photon flux ( $N^{usual}$ ) emitted by the projectile nucleus, only the photons that reach the geometric region of the target nucleus will be considered;
- Photons that reach the nuclear superposition region will be discarded (dominated by the strong interaction).

effective photon flow:

$$N^{eff}(\omega, b) = \int N^{usual}(\omega, b_1) \frac{\theta(b_1 - R_A) \theta(R_A - b_2)}{A_{eff}(b)} d^2 b_2$$

spectators area:

$$A_{eff}(b) = R_A^2 \left[ \pi - 2 \cos^{-1} \left( \frac{b}{2R_A} \right) \right] + \frac{b}{2} \sqrt{4R_A^2 - b^2}$$

The effective photonuclear cross section

- Applying the same geometric constraint on the photonuclear cross section.
  - The dipole-core interaction will be restricted to only the dipole interaction with the part of the core that forms the spectator region

$$\sigma_{\text{dip}}^{\text{nucleus}}(x, r) = 2 \int d^2b_2 \Theta(b_1 - R_A) \left\{ 1 - \exp \left[ -\frac{1}{2} T_A(b) \sigma_{\text{dip}}^{\text{proton}}(x, r) \right] \right\}$$

$$b_1^2 = b^2 + b_2^2 + 2bb_2 \cos(\alpha)$$

Summary

- In pQCD and QCD models
- Linear and non-linear evolution equations.
- The data favour those models featuring moderate nuclear shadowing.

S. Ragoni, on behalf of the ALICE

Collaboration, arXiv:2305.03616v1

- In pQCD
- The  $|\text{Re}(M)|^2$  in LO is almost irrelevant.

Summary

- New LHCb forward data agrees with ALICE data also at forward direction. Sensitive to  $\mu$  choice.

- However, large uncertainties remain due to the nuclear PDFs. A comparison between EPPS21, nNNPDF3.0 and nCTEQ15WZSIH uncertainties is shown.

Section

Summary

- Coherent  $J/\psi$  is sensitive to the average of spatial distribution of the gluons.

- Incoherent  $J/\psi$  is sensitive to the gluons variance.

None of the models manages to describe

both the slope and the normalization of the data distribution.

- It is a powerful observable to measure gluon saturation.

Summary

FoCal calorimeter consist of two calorimeters, an electromagnetic calorimeter (FoCal-E) and an hadronic calorimeter (FoCal-H), intended to be installed in the ALICE experiment in 2026.

The FoCal-E will be a sampling calorimeter made of tungsten and silicon.

The FoCal-H will be a sampling calorimeter "spaghetti" model made of lead and scintillating fibers.

With FoCal, it will be possible to study the  $J/\psi$  mesons through their decay into  $e^+e^-$  pairs, which can be detected by the calorimeter through the production of electromagnetic showers.

- Simulation using STARlight to generate  $J/\psi$  and  $\psi'$  events. Where the data is grouped into superclusters and matched with the physical primary particles;
- Expected yields result in a clear separation between the resonances.

Summary

Conclusions

- Exclusive quarkonium photoproduction off protons in p-Pb UPC
  - Probe the gluon density at low  $x$
  - Search for gluon saturation effects
- Light vector mesons photoproduction in UPC provides
  - Test theoretical models
  - Study shadowing effects in the nonperturbative regime
- Photoproduction in peripheral collisions
  - Complements the knowledge on hadroproduction
  - Learning on nuclear medium and quark gluon plasma
- LO calculations require comparison to NLO
  - Role of quark contribution in heavy vector meson production
  - Confrontation data on different energies,  $y$ 's, centralities...

# And a Look Ahead...

Introduction

UPC  
Collisions

Peripheral  
Collisions

Summary

Conclusions

- UPC Pb-Pb collisions for exclusive coherent  $J/\psi$ , the current data cannot distinguish between NLO pQCD and LO dipole models.
- $J/\psi$  photoproduction within NLO dipole picture requires the relativistic correction  $v^2$  as well as longitudinal vector meson function at NLO to describe the data.
- FoCal is the best suited LHC detector subsystem to exploit this energy; it will probe the gluon densities of protons and heavy ions down to Bjorken-x values below  $10^{-6}$ .
